

A CRYOARRAY SYSTEM AND USES THEREOF

5

BACKGROUND OF THE INVENTION

Cross-Reference to Related Applications

This application claims benefit of priority of provisional U.S. Serial Number 60/250,084, filed November 30, 2000, now abandoned.

Field of the Invention

The present invention relates generally to the field of molecular pathology and biomedical devices. More specifically, the present invention relates to a cryoarray device/system for creating frozen tissue arrays for subsequent assaying.

Description of the Related Art

The implementation of high-throughput genetic technologies, such as oligonucleotide microarrays, generates myriad points of data. The identified potential candidate genes need to be
5 further characterized and selected using a large number of well-characterized tumors and stringent criteria. Tissue microarrays allow for such high-throughput expression profiling of tumor samples, additionally providing information at the microanatomical level.

Sections cut from tissue arrays allow parallel detection of DNA, e.g., by fluorescence *in-situ* hybridization (FISH), RNA, e.g., by mRNA *in-situ* hybridization (mRNA ISH) or protein, e.g., by immunohistochemistry (IHC) targets in each of the multiple
15 specimens in the array. Each microarray block can be sectioned up to 200-300 times. Therefore, tens of thousands of tissue microarray sections can be obtained from a set of tissue specimens in one recipient block. This substantially facilitates molecular profiling of very large numbers of cancer tissues and allows the generation of
20 large-scale correlative databases including clinical information and molecular data (including images), while ensuring that the donor

blocks from which the tissue cores are removed can continue to be utilized so that research materials are not destroyed.

In early 1998, Kononen et al. (1) described a tissue microarray "chip" that had been developed for high-throughput molecular profiling of tumor specimens. Tissue microarrays enable rapid *in-situ* analysis of up to 1000 tumors or other tissues in a single experiment. In the method of Kononen, original tissue sample sources are morphologically representative regions of regular formalin-fixed paraffin-embedded tumor blocks. Core tissue biopsies are taken from individual "donor" paraffin-embedded tumor blocks and precisely arrayed into a new "recipient" paraffin block using a custom built instrument. Thereafter, Bubendorf et al. published data of a survey of gene amplifications during prostate cancer progression by high-throughput fluorescence *in-situ* hybridization on tissue microarrays (2). The first hand-held paraffin tissue array apparatus was later marketed.

Tissue microarrays consisting of 0.6 mm biopsies of paraffin-embedded tissues have been used for various clinicopathological studies. This size is sufficient for assessing morphological features of the analyzed tissues on many samples.

However, the size of the biopsy used in these arrays may not be representative of the whole tumor specimen because of tissue heterogeneity. Additionally, paraffin tissue arrays have distinct limitations in maintaining intact RNA transcription levels, as well as proteins and other molecules (i.e., lipids) due to the fixatives and chemical reagents required for the paraffin process. Thus, tissue microarray technology using paraffin-embedded tissues can reach its limits for the detection of RNA targets or certain proteins. The use of a cryoarray strategy would overcome these limitations and would allow for the processing of multiple frozen tissue specimens and/or cell lines on a single tissue block.

Therefore, it would be beneficial to have an effective means and a system for creating tissue arrays that allow all molecules to be assayed at the expression level and simultaneously visualized at micro-anatomical levels. Specifically, the prior art is deficient in the lack of an effective means/system for creating a cryoarrays for frozen tissue assays. The present invention fulfills this long-standing need and desire in the art.

SUMMARY OF THE INVENTION

In one embodiment of the present invention, there is provided a cryoarray device comprising a mold plate having an upper and a lower surface; mold alignment pins where the mold alignment pins are perpendicularly attached to the lower surface of the mold plate; an ejector plate having an upper surface and a lower surface where the plate has holes between the upper surface and the lower surface; ejector pins having ejector thumb pads attached to an upper surface of the ejectors pins and connecting the mold plate and the ejector plate; and cryoarray pins, of equal number to the holes in the ejector plate and aligned with the holes in the ejector plate.

In another embodiment of the present invention, there is provided a cryoarray system for forming an array for frozen tissue, comprising a tissue mold; an embedding medium filling the tissue mold, frozen within the tissue mold where the frozen embedding medium forms a recipient tissue block; and the cryoarray device which is placed in the tissue mold containing the embedding medium, but prior to freezing the embedding medium; where freezing the embedding medium around the cryoarray pins of the

device creates grid holes into the recipient block when the cryoarray device is separated from the recipient block so that an array is formed in the recipient block for frozen tissue.

5 In yet another embodiment of the present invention, there is provided a method for preparing tissue for assays, comprising the steps of selecting at least one frozen tissue core from a donor block; inserting each of the frozen cores into a grid hole of the recipient block of the cryoarray system disclosed *supra* thereby forming a frozen tissue array; cutting sections from the array; and assaying the sections.

100577E-4340045 Other and further aspects, features, and advantages of the present invention will be apparent from the following description of the presently preferred embodiments of the invention given for the purpose of disclosure.

BRIEF DESCRIPTION OF THE DRAWINGS

So that the matter in which the above-recited features, advantages and objects of the invention, as well as others which will become clear, are attained and can be understood in detail, more particular descriptions of the invention briefly summarized above may be had by reference to certain embodiments thereof which are illustrated in the appended drawings. These drawings form a part of the specification. It is to be noted, however, that the appended drawings illustrate preferred embodiments of the invention and therefore are not to be considered limiting in their scope.

Figure 1 shows an over view of the cryoarray apparatus **100**, comprising a mold plate **102**, an ejector plate **104**, two ejector/guide springs **106**, two ejector/guide pins **108**, two ejector thumb pads **110**, twelve cryoarray pins **112**, two mold alignment pins **114**, and two ejector screws **116**.

Figure 2 shows another over view of the cryoarray apparatus **100** from a different angle, which is an upside-down position compared to the view in Figure 1.

DETAILED DESCRIPTION OF THE INVENTION

In one embodiment of the present invention, there is provided a cryoarray device comprising a mold plate having an upper and a lower surface; mold alignment pins where the mold alignment pins are perpendicularly attached to the lower surface of the mold plate; an ejector plate having an upper surface and a lower surface where the plate has holes between the upper surface and the lower surface; ejector pins having ejector thumb pads attached to an upper surface of the ejectors pins and connecting the mold plate and the ejector plate; and cryoarray pins, of equal number to the holes in the ejector plate and aligned with the holes in the ejector plate.

In an aspect of this embodiment the mold alignment pins direct the placement of the cryoarray device into a tissue mold. Additionally, the cryoarray pins connect operably to the lower surface of the mold plate and are capable of passing through the holes in said ejector plate. In this aspect the ejector pins are capable of lowering and of raising the ejector plate over the cryoarray pins. Optionally, the cryoarray device may have ejector springs that surround an outer surface of the ejector pins and operably located

between the upper surface of the mold plate and the lower surface of one of the ejector thumb pads.

In another embodiment of the present invention, there is provided a cryoarray system for forming an array for frozen tissue, comprising a tissue mold; an embedding medium filling the tissue mold, frozen within the tissue mold where the frozen embedding medium forms a recipient tissue block; and the cryoarray device is placed in the tissue mold containing the embedding medium, but prior to freezing the embedding medium; where freezing the embedding medium around the cryoarray pins of the device creates grid holes into the recipient block when the cryoarray device is separated from the recipient block so that an array is formed in the recipient block for frozen tissue.

In this embodiment of the present invention the recipient block is separated from the cryoarray device by depressing the ejector pins to lower the ejector plate over the cryoarray pins. A representative example of the embedding medium is O.C.T.TM compound. The embedding medium is frozen at temperature of about -20 °C to about -80 °C.

In yet another embodiment of the present invention, there is provided a method for preparing tissue for assays, comprising the steps of selecting at least one frozen tissue core from
5 a donor block; inserting each of the frozen cores into a grid hole of the recipient block of the cryoarray system disclosed *supra* thereby forming a frozen tissue array; cutting sections from the array; and assaying the sections. Representative diameters for the frozen tissue core samples to be assayed are about 1.0 mm to about 3.0 mm in
10 diameter, preferably about 2.5 mm to about 3.0 mm in diameter. Examples of tissue assays that can be performed on the tissue array are morphologic evaluation, *in situ* hybridization, immunohistochemistry, *in situ* polymerase chain reaction and fluorescence *in situ* hybridization.

Provided herein is cryoarray device/system for forming frozen tissue arrays for subsequent analysis. When comparing the instant cryoarray to a paraffin-embedded array, even if the number of specimens that can be analyzed per array is lower than that with
20 paraffin tissue arrays, the cryoarray system provides a significant advantage. Because a core diameter of 3 mm is used in the instant

cryoarrays, it may not be necessary to array more than one or two biopsies per specimen, thus increasing the efficiency in comparison with paraffin tissue arrays. Additional advantages of the instant cryoarrays include the use of multiple fixatives to optimize immunohistochemistry (IHC) or *in-situ* hybridization (ISH) for target probe or antibody assays and the use of the very same samples on which immunohistochemistry or *in-situ* hybridization is carried out to extract RNA to make cDNA for gene microchip analysis. Embodiments of the present invention are better illustrated with reference to the Figures, however, such reference is not meant to limit the present invention in any fashion.

A representative cryoarray design is shown in Figures 1 - 3. The cryoarray apparatus 100 comprises a mold plate 102, an ejector plate 104, two ejector/guide springs 106, two ejector/guide pins 108, two ejector thumb pads 110, twelve cryoarray pins 112, two mold alignment pins 114, and two ejector screws 116. Furthermore, although the apparatus 100 depicted herein comprises twelve cryoarray pins 112, the number of pins in the cryoarray need not be limited to twelve, e.g., a forty-eight compartment cryoarray can increase the number of cores in a cryoarray, thereby

increasing the size of the assay data set. The diameter of the cryoarray pins 112 is about 3 mm. Table 1 lists each component of the cryoarray as well as the material of which each component is made.

5

TABLE 1

Components of Cryoarray System 100

Reference #	Title	Material	Quantity
102	Mold Plate	Brass	1
104	Ejector Plate	Brass	1
106	Ejector/Guide Spring	Stainless Steel	2
108	Ejector/Guide Pin	Stainless Steel	2
112	Cryoarray Pin (variable number)	Stainless Steel	12 (as shown)
114	Mold Alignment Pin	Stainless Steel	2
110	Ejector Thumb Pad	Brass	2
116	Ejector Screw	Stainless Steel	2

10

With reference to Figure 4 and continued reference to Figures 1-3, the cryoarray apparatus **100** is used with a tissue mold (not shown) to form a cryoarray or frozen tissue array system comprising a single recipient block **200** of arrayed multiple biopsies taken from embedded frozen tissues. The recipient block **200** is a frame of embedding compound **202** containing multiple preformed holes **204** having a diameter of about 3.0 mm.

As is standard in the art, a plastic mold for frozen tissue is filled with a liquid embedding medium to the fill line indicated on the tissue mold. A representative example of a tissue mold is Cryomold having 37 cm x 24 cm dimensions (Simport, Montreal, Canada) and of an embedding medium is optimal cutting temperature compound or O.C.T.TM compound (SAKURA FINETEK, Torrance, CA). O.C.T.TM compound has a freezing point of 0 °C.

The cryoarray apparatus **100** is placed into the Cryomold (not shown) as directed by the mold alignment pins **114**. The cryoarray pins **112** displace the liquid embedding compound and create a grid of holes **204** framed by the embedding compound **202**. The tissue mold containing the cryoarray **100** is then placed at about

known to one of ordinary skill in the art. The core samples 206 preferably have a diameter of about 2.5 mm to 3.0 mm. It is to be understood that when using the cryoarray 200, frozen cores of less than 1 mm in diameter usually become friable and can break apart.

5 Thus, a particularly fine needle diameter may be optimal for removing a frozen core from donor blocks.

The further processing of the cryoarray 200 follows the general guidelines for embedded frozen tissue samples, particularly for samples embedded in O.C.T.[™]. Frozen sections are generated using a tape-based sectioning system (Instrumedics, Hackensack, NJ). Sections cut from the cryoarray 200 allow parallel detection of DNA (e.g. by fluorescence *in-situ* hybridization), RNA (e.g. by mRNA ISH) or protein (e.g. by immunohistochemical analysis) targets in each of the specimens 206 in the cryoarray 200. Figure 7 depicts a hematoxylin and eosin stained section of the frozen tissue specimen 206.

Cell proliferation, differentiation, death and genomic integrity is controlled by a multitude of genes and signaling pathways in cancer development. Through new techniques, such as

cDNA microarrays, the expression of thousands of genes can be measured in a single experiment. As such, analysis of thousands of specimens from patients at different stages of disease can be comprehensively surveyed. The potential uses of the cryoarray disclosed herein include analyzing molecular basis of tumor progression; obtaining molecular profiling of thousands of tumors with hundreds of biomarkers; validation of cDNA microarray screening data; rapid translation of results from cell line and animal models to human cancer; evaluation of the diagnostic, prognostic and therapeutic potential of newly discovered genes and molecules; testing and optimization of probes and antibodies; improved utilization of pathology archives and tissue banks; and international, large scale collaborations for multi-center molecular profiling of tumors.
